Abstract

We have recently proposed a generalized JKR model for non-slipping adhesive contact between two elastic spheres subjected to a pair of pulling forces and a mismatch strain (Chen, S., Gao, H., 2006c. Non-slipping adhesive contact between mismatched elastic spheres: a model of adhesion mediated deformation sensor. J. Mech. Phys. Solids 54, 1548–1567). Here we extend this model to adhesion between two mismatched elastic cylinders. The attention is focused on how the mismatch strain affects the contact area and the pull-off force. It is found that there exists a critical mismatch strain at which the contact spontaneously dissociates. The analysis suggests possible mechanisms by which mechanical deformation can affect binding between cells and molecules in biology.

Keywords: Adhesion; Contact; Deformation; JKR model; Biological materials

1. Introduction

The last few decades have witnessed significant progresses in the mechanics of adhesive contact between elastic bodies (Johnson et al., 1971; Derjaguin et al., 1975; Roberts and Thomas, 1975; Muller et al., 1980; Greenwood and Johnson, 1981; Barquins, 1988; Maugis, 1992; Carpick et al., 1996; Chaudhury et al., 1996; Baney and Hui, 1997; Greenwood, 1997; Johnson and Greenwood, 1997; Barthel, 1998; Robbe-Valloire and Barquins, 1998; Greenwood and Johnson, 1998; Kim et al., 1998; Shull, 2002; Morrow et al., 2003; Schwarz, 2003). More recently, various contact mechanics theories have also been developed to understand the basic principles behind hierarchical adhesion structures of gecko and insects (Autumn et al., 2002; Artz et al., 2003; Persson, 2003; Gao and Yao, 2004; Glassmaker et al., 2004; Hui et al., 2004; Gao et al., 2005; Huber et al., 2005; Spolenak et al., 2005; Yao and Gao, 2006). Most of the existing models on contact...
mechanics have focused on the normal tractions inside the contact region (Johnson, 1985). On the other hand, recent studies on elastic bodies in non-slipping adhesive contact with a laterally stretched substrate (Chen and Gao, 2006a,b) indicate that the substrate strain can have significant effect on the contact area. Further study on the pull-off process of two elastic spheres in non-slipping adhesive contact under a pair of pulling forces and a mismatch strain suggests that the mismatch strain can play a dominant role in adhesion (Chen and Gao, 2006c). For example, as the mismatch strain is increased, the contact area is found to continuously decrease until the contact suddenly breaks off at a critical strain. These studies suggest possible connections to general observations in biology that cells and biomolecules can sense and react to mechanical signals in the environment.

The present paper extends our previous analysis of non-slipping adhesive contact between mismatched elastic spheres (Chen and Gao, 2006c) to the corresponding plane strain problem of contact between elastic cylinders. In contrast to the classical JKR model, we assume that the contact area is perfectly bonded such that both tangential and normal tractions are transmitted across the contact interface. This assumption has been inspired by specific ligand–receptor binding in cell adhesion as well as specific sequence matching in adhesion between biomolecules. If there is one to one bonding between specific molecules, shear deformation along the contact interface would not be easily relaxed. The focus of the present study is on how the mismatch strain influences the contact area and the pull-off force between two adhering cylinders.

2. Model

Fig. 1 shows two dissimilar elastic cylinders that are brought into adhesive contact and then subjected to the combined action of a pair of pulling forces $F$ and a mismatch strain $\varepsilon$. The contact region is assumed to be perfectly bonded except that the edge of contact is allowed to shift according to the changing balance between elastic energy and surface energy in the system.

![Fig. 1. Schematic of two adhering elastic cylinders acted by a pair of forces $F$ and a mismatch strain $\varepsilon$. $(E_1, v_1), (E_2, v_2)$ denote Young's moduli and Poisson's ratio of the cylinders; $a$ is the half-width of the contact region.](image-url)
A pair of Cartesian coordinates \((x, y_1), (x, y_2)\) are placed at the center of the contact region of each cylinder, with \(y_1\) and \(y_2\) pointing into each corresponding body. The Young’s moduli and Poison ratios of the upper and lower cylinders will be denoted as \(E_1, v_1\) and \(E_2, v_2\), respectively; \(R_1\) and \(R_2\) are the radius of each cylinder; \(a\) is the half-width of the contact area; \(\sigma_{y_1}(x)\) and \(\sigma_{y_2}(x)\) are the normal and tangential tractions along the contact surface of the upper cylinder inside the contact area. This contact model resembles an external interfacial crack problem under plane strain deformation, in which the stress field near the crack tip is known to exhibit an oscillatory singularity (Rice, 1965; Erdogan, 1965; Westmann, 1965).

3. General solution

Under a mismatch strain (e.g., due to change in pressure or temperature in the environment), the relative tangential displacement and displacement gradient in the adhesion zone satisfy

\[
\bar{u}_{y1} - \bar{u}_{y2} = \bar{e}, \quad \frac{\partial \bar{u}_{y1}}{\partial x} - \frac{\partial \bar{u}_{y2}}{\partial x} = \bar{e}, \quad |x| \leq a. \tag{1}
\]

The normal tractions in the contact area cause the surface of each body to be displaced parallel to the \(y_i\) \((i = 1, 2)\) axis (measured positive into each body) by an amount \(\bar{u}_{y1}\) and \(\bar{u}_{y2}\). According to the usual parabolic assumption of local contact surfaces (Johnson, 1985),

\[
\bar{u}_{y1} + \bar{u}_{y2} = \delta - \frac{x^2}{2R}, \quad \frac{\partial \bar{u}_{y1}}{\partial x} + \frac{\partial \bar{u}_{y2}}{\partial x} = -\frac{x}{R}, \quad |x| \leq a, \tag{2}
\]

where \(R\) is the combined radius defined by \(1/R = 1/R_1 + 1/R_2\) and \(\delta\) is the relative displacement at the center of the contact region.

Using the plane strain elastic Green’s functions of half-spaces, the displacement gradients in Eqs. (1) and (2) can be expressed in terms of normal and tangential tractions as

\[
\begin{align*}
\frac{1}{\pi} \int_{-a}^{a} \sigma_{y_1}(s) \frac{1}{s - x} ds - \beta \sigma_{y_2}(x) &= \frac{E^* \bar{e}}{2}, \quad |x| \leq a, \\
\frac{1}{\pi} \int_{-a}^{a} \sigma_{y_2}(s) \frac{1}{s - x} ds + \beta \sigma_{y_1}(x) &= -\frac{E^* x}{2R},
\end{align*}
\tag{3}
\]

where

\[
E^* = \frac{1 - v_1^2}{E_1} + \frac{1 - v_2^2}{E_2}
\tag{4}
\]
is the combined Young’s modulus and

\[
\beta = \frac{E^*}{2} \left\{ \frac{(1 - 2v_1)(1 + v_1)}{E_1} - \frac{(1 - 2v_2)(1 + v_2)}{E_2} \right\}
\tag{5}
\]
is one of Dundurs’ elastic constants for biomaterial systems (Dundurs, 1969).

Eqs. (3) are coupled integral equations for the two unknown tractions \(\sigma_{y_1}(x)\) and \(\sigma_{y_2}(x)\). It is convenient to rewrite Eqs. (3) in a matrix form (Chen and Gao, 2006a)

\[
\frac{1}{\pi} \int_{-a}^{a} \frac{A}{s - x} f(s) ds + Bf(x) = C,
\tag{6}
\]

where

\[
f(s) = \begin{pmatrix} \sigma_{y_1}(s) \\ \sigma_{y_2}(s) \end{pmatrix}, \quad A = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = I, \quad B = \begin{bmatrix} 0 & -\beta \\ \beta & 0 \end{bmatrix}, \quad C = \begin{bmatrix} E^* \bar{e} \\ \frac{E^* x}{2R} \end{bmatrix}.
\tag{7}
\]

Using Hilbert transform

\[
F_k(z) = \frac{1}{2\pi i} \int_{-a}^{a} \frac{f_k(s)}{s - z} ds, \quad k = 1, 2,
\tag{8}
\]
where $z = x + iy$ and $i = \sqrt{-1}$, Eq. (6) can be decoupled into two inhomogeneous Hilbert equations to be solved together with boundary conditions
\[
\int_{-a}^{a} \sigma_{yy}(x) dx = -F \int_{-a}^{a} \sigma_{yy}(x) dx = 0.
\]  
(9)

The solution procedure for this problem is similar to that discussed in Chen and Gao (2006a). Here we skip the details and present only the final solution. The interfacial tractions in the contact region can be expressed in the form
\[
\sigma_{yy}(x) + i\sigma_{xy}(x) = 2I(x) + \frac{E'\beta}{2(1-\beta^2)} \left( \frac{x}{R} + \frac{i}{R} \right) - \frac{E(a + x)^{-\gamma}(a - x)^{-\gamma}}{\pi},
\]  
(10)

where
\[
I(x) = -\frac{E'(a + x)^{-\gamma}(a - x)^{-\gamma}}{4\pi(1-\beta^2)} \left[ \int_{-a}^{a} \left( \frac{x}{R} + \frac{i}{R} \right) \frac{(a + t)^{\gamma}(a - t)^{\gamma}}{t - x} dt \right],
\]  
(11)

and $r$ is the stress singularity, $\kappa$ is the so-called oscillatory index,
\[
r = \frac{1}{2} + i\kappa, \quad \kappa = \frac{1}{2\pi} \ln \frac{1 + \beta}{1 - \beta}.
\]  
(12)

The associated stress intensity factor can be calculated as
\[
K = -\sqrt{2\pi} \lim_{x \to a} (a - x)^{\gamma} [\sigma_{yy}(x) + i\sigma_{xy}(x)] = \frac{-iE'(2a)^{-\gamma}}{\sqrt{2\pi(1-\beta^2)}} \int_{-a}^{a} \left( \frac{\varepsilon + \frac{i}{R}(a + t)^{\gamma}(a - t)^{\gamma}}{a - t} \right) dt + \frac{\sqrt{2}F(a)^{-\gamma}}{\sqrt{\pi}},
\]  
(13)

which when substituted into Griffith's condition
\[
G = \frac{1}{\cosh^2 \pi \kappa} \frac{|K|^2}{2E'} = \Delta_Y,
\]  
(14)

leads to the following relationship between the equilibrium contact half-width $a$, the mismatch strain $\varepsilon$ and the external pulling force $F$,
\[
\left| \frac{iE}{2(\beta^2 - 1)} \left( \frac{a}{R} \right)^{\frac{1}{2}} \int_{-1}^{1} \frac{(1 + \xi)^{\gamma}(1 - \xi)^{\gamma}}{1 - \xi} d\xi + \frac{F}{E'R} \left( \frac{R}{a} \right)^{\frac{1}{2}} \int_{-1}^{1} \frac{\xi(1 + \xi)^{\gamma}(1 - \xi)^{\gamma}}{1 - \xi} d\xi \right|^2 = 2\cosh^2(\pi \kappa) \frac{\pi \Delta_Y}{E'R},
\]  
(15)

where $\Delta_Y$ denotes the work of adhesion.

4. Non-oscillatory solution

It has been shown that Dundurs' parameter $\beta$ only plays a minor role in non-slipping adhesive contact (Chen and Gao, 2006a,b,c) and may be neglected for practical purposes. In the case of $\beta = 0$, the tangential and normal tractions inside the contact region are reduced to simpler forms,
\[
\sigma_{xy}(x) = \frac{E'\varepsilon x}{2\sqrt{a^2 - x^2}},
\]  
(16)
\[
\sigma_{yy}(x) = \frac{-E'\varepsilon x^2 - a^2/2}{2R \sqrt{a^2 - x^2}} - \frac{F}{\pi\sqrt{a^2 - x^2}},
\]  
(17)

with stress intensity factors
\[
K_I = \frac{E'\varepsilon \sqrt{\pi a^{3/2}}}{4R} + \frac{F}{\sqrt{\pi a}},
\]  
(18)
\[
K_{II} = -\frac{E'\varepsilon \sqrt{\pi a}}{2}.
\]  
(19)
The mode I solution of Eq. (18) is consistent with that given in Chaudhury et al. (1996) and the mode II solution of Eq. (19) is consistent with a similar solution for external crack given in Tada et al. (2000). Inserting Eqs. (18) and (19) into the corresponding Griffith condition in the non-oscillatory case,

\[ G = \frac{(K_1^2 + K_{11}^2)}{2E'} = \Delta \gamma, \]

leads to the following equation

\[ a^3 + 4R^2 \varepsilon^2 a + \frac{8RFa}{\pi E'} - \frac{32\Delta \gamma R^2}{\pi E'} + \frac{16R^2F^2}{\pi^2 E' a} = 0, \]

for determining the contact half-width \( a \) as a function of the mismatch strain \( \varepsilon \) and the pulling force \( F \).

In the case of \( \varepsilon = 0 \), it can be shown that the non-oscillatory solution is identical to the 2D JKR solution of Chaudhury et al. (1996), i.e., \( a_{e=0} = a_{JKR} \). In this case, the relationship between the contact size and the pulling force can be expressed as

\[ F = \frac{-\pi E' a_{JKR}^2}{4R} + \sqrt{2\pi E' a_{JKR} \Delta \gamma}. \]

Eq. (21) can be normalized as

\[ \tilde{a}^3 + 4\lambda^2 \varepsilon^2 \tilde{a} - 1 + 64m^2 \left( \frac{1}{\tilde{a}} - 1 \right) - 16m(1 - \tilde{a}) = 0, \]

where

\[ \tilde{a} = \frac{a}{a_{JKR}}, \quad \lambda = \frac{R}{a_{JKR}}, \quad m = \frac{FR}{2\pi E' a_{JKR}}. \]

5. Discussion

5.1. The \( \varepsilon = 0 \) case

In the case of \( \varepsilon = 0 \), the stress intensity factor is

\[ K = \frac{E'(2a)^{-\varepsilon}}{\sqrt{2\pi(1 - \beta^2)R}} \int_{-a}^a t(a + t)^{\varepsilon}(a - t)^{\varepsilon} \frac{dt}{a - t} \frac{\sqrt{2(2a)^{-\varepsilon}F}}{\sqrt{\pi}}. \]

Inserting this into the Griffith condition (14) yields

\[ \left[ \frac{1}{2\sqrt{\pi}(1 - \beta^2)} \left( \frac{a_0}{R} \right)^\frac{1}{2} \int_{-1}^1 \frac{\tilde{\xi}(1 + \tilde{\xi})^{\varepsilon}(1 - \tilde{\xi})^{\varepsilon}}{1 - \tilde{\xi}} d\tilde{\xi} + \left( \frac{R}{a_0} \right)^\frac{1}{2} \frac{F}{E'R\sqrt{\pi}} \right]^2 = 2\cosh^2(\pi \kappa \frac{\Delta \gamma}{E'R}), \]

where \( a_0 \) denotes the contact size for the case \( \varepsilon = 0 \). This equation can be normalized as

\[ \left[ \frac{1}{2\sqrt{\pi}(1 - \beta^2)} \frac{\tilde{a}^2 \lambda^{-1}}{16} \int_{-1}^1 \frac{\tilde{\xi}(1 + \tilde{\xi})^{\varepsilon}(1 - \tilde{\xi})^{\varepsilon}}{1 - \tilde{\xi}} d\tilde{\xi} + \tilde{a}^2 \lambda \frac{F}{E'R\sqrt{\pi}} \right]^2 \]

\[ = \cosh^2(\pi \kappa) \left[ \frac{\pi}{16} \lambda^{-2} + \lambda^2 \frac{F^2}{\pi E'^2 R^2} + \frac{1}{2} \frac{F}{E'} \right], \]

where

\[ \tilde{a} = \frac{a_0}{a_{JKR}}, \quad \lambda = \frac{R}{a_{JKR}}. \]

Numerical evaluation of (27) indicates that the ratio \( a_0/a_{JKR} \) is close to 1. Fig. 2 plots \( a_0/a_{JKR} \) for a fixed value of \( \lambda \) and three values of \( F/(E'R) \). It can be seen that the non-oscillatory solution, which for the case \( \varepsilon = 0 \) corresponds to the JKR model, serves as a good approximate solution to the non-slipping adhesion problem.
5.2. Effect of mismatch strain

In the presence of a mismatch strain, the coupling between shear and normal tractions in the contact area becomes important. In this case, the contact half-width $a$ is related to the mismatch strain $\varepsilon$ and the external force $F$ according to Eq. (15) which can be normalized as

$$
\frac{\tilde{a} \tilde{\lambda} a_{JKR}^{3}}{2 \sqrt{\pi (\beta^2 - 1)}} \int_{-1}^{1} \frac{(1 + \tilde{\varepsilon})(1 - \tilde{\varepsilon})}{1 - \tilde{\varepsilon}} d\tilde{\varepsilon} + \frac{\tilde{a}^2}{2 \sqrt{\pi (1 - \beta^2)}} \int_{-1}^{1} \frac{\tilde{\varepsilon}(1 + \tilde{\varepsilon})(1 - \tilde{\varepsilon})}{1 - \tilde{\varepsilon}} d\tilde{\varepsilon} + \frac{FR}{\sqrt{\pi E^* a^2}} \right|^2
$$

where

$$
\tilde{a} = a/a_0 \approx a/a_{JKR}, \quad \lambda = R/a_0 \approx R/a_{JKR}.
$$

Numerical evaluation of the above equation indicates that Dundurs’ parameter $\beta$ only plays a minor role and can be neglected so that the non-oscillatory Eq. (23) can be used as a reasonable approximation. An example of comparison between the fully couple solution and the non-oscillatory solution is shown in Fig. 3 for $\beta = 0, 0.25$ and $-0.25$.

The non-oscillatory solution expressed in Eqs. (23) and (24) indicates that, for a given non-dimensional parameter $FR/(2\pi E^* a^2_{JKR})$, the normalized contact half-width $a/a_{JKR}$ depends on the mismatch strain $\varepsilon$ only through the parameter combination $\lambda \varepsilon$. Fig. 4 plots the relation between $a/a_{JKR}$ and $\lambda \varepsilon$ for several values of the pulling force.

Assuming $\beta = 0$, the generalized JKR model for adhesive contact boils down to the following relation

$$
F = \frac{-\pi E^* a^2}{4R} + \sqrt{2\pi E^* \Delta \gamma a - \frac{\pi^2 E^* \varepsilon^2 a^2}{4}}.
$$

Fig. 5 shows the calculated relation between the normalized contact half-width $a/R$ and the normalized external force $F/\Delta \gamma$ for different mismatch strains and a fixed non-dimensional parameter $E^* R/\Delta \gamma$. The mismatch strain is seen to exert significant influence on the pull-off process.

For different values of $E^* R/\Delta \gamma$, Fig. 6 shows the behavior of the normalized pull-off force $F/\Delta \gamma$ as a function of the mismatch strain $\varepsilon$; similarly, Fig. 7 shows the behavior of the normalized critical contact half-width at pull-off. The pull-off force is seen to decrease with increasing mismatch strain. For a given mismatch strain, the normalized pull-off force increases with the non-dimensional parameter $E^* R/\Delta \gamma$. On the other hand, for a
Fig. 3. Variation of normalized contact half-width $a/a_0$ with $\lambda e$ as predicted by Eq. (29) of the text for different values of $\beta$ and fixed values of $FR/(E^*a_0^2)$ and $\lambda$. The results indicate that the influence of $\beta$ is small and can be neglected.

Fig. 4. Variation of $a/a_{JKR}$ via $\lambda e$ ($\lambda = R/a_{JKR}$) for different values of $FR/(2\pi E^*a_{JKR}^2)$. Under a finite pulling force, the contact size decreases with increasing $e$ and an instability occurs at a critical value of $e$.

Fig. 5. Normalized contact half-width $a/R$ as a function of the normalized pulling force $F/\Delta y$ for different mismatch strains and a fixed value of $E^*R/\Delta y$. 
given pulling force, there always exists a critical mismatch strain $\varepsilon$ at which two adhering cylinders will spontaneously break apart. Fig. 7 shows that the normalized critical contact half-width $a/R$ at pull-off is also influenced by the mismatch strain: the critical contact width decreases with increasing mismatch strain. For a given mismatch strain, the critical contact width decreases with increasing $E^* R/\Delta \gamma$.

### 5.3. Adhesion mediated deformation sensor

The present analysis suggests that, under plane strain conditions, two adhering elastic bodies under a pair of pulling forces have an increasing chance to break up in the presence of a mismatch strain. Thermal forces tend to break apart any adhering objects and are therefore analogous to pulling forces considered in the present model. Mismatch strains can be generated by changes in environment pressure or temperature or PH values. These results are similar to our previous analysis with respect to two adhering spheres (Chen and Gao, 2006c).

For a given mismatch strain with no applied pulling force, the adhesion energy can be estimated as

$$\Delta U = \Delta U_{\text{surface}} - \Delta U_{\text{elastic}},$$

where $\Delta U_{\text{surface}}$ is the change in surface energies and $\Delta U_{\text{elastic}}$ is the change in elastic energy as the contact is formed. These quantities can be calculated as
\[ \Delta U_{\text{surface}} = 2a_{\text{eq}}\Delta \gamma, \]  
\[ \Delta U_{\text{elastic}} = 2 \int_{a_{\text{eq}}}^{a_{\text{eq}}} G|_{F=0} \, da, \]  
where

\[ G|_{F=0} = \frac{K_1^2 + K_{II}^2}{2E} \]  
is the strain energy release rate when \( F = 0, \varepsilon \neq 0 \) and \( a_{\text{eq}} \) is the corresponding equilibrium contact half-width that can be obtained from Eq. (23) as,

\[ a_{\text{eq}} = a_{\text{JKR}} \left[ \frac{1}{2} + \sqrt{\frac{1}{4} + \frac{64\lambda^2 \varepsilon^6}{27}} \right]^{1/3} - \frac{4\lambda^2 \varepsilon^2}{3} \left[ \frac{1}{2} + \sqrt{\frac{1}{4} + \frac{64\lambda^2 \varepsilon^6}{27}} \right]^{-1/3}, \]  
where

\[ a_{\text{JKR}} = \left[ \frac{32R^2 \Delta \gamma}{\pi E^*} \right]^{1/3}. \]  
The corresponding stress intensity factors can be expressed from Eqs. (18) and (19) as

\[ K_1 = \frac{E^* \sqrt{\pi a^{3/2}}}{4R}, \quad K_{II} = -\frac{E^* \varepsilon \sqrt{\pi a}}{2}, \]  
Therefore,

\[ \Delta U_{\text{elastic}} = \left( \frac{a_{\text{eq}}^2}{8R^2} + \varepsilon^2 \right) \frac{\pi E^* a_{\text{eq}}^2}{8}, \]  
and the total adhesion energy is

\[ \Delta U = 2a_{\text{eq}}\Delta \gamma - \left( \frac{a_{\text{eq}}^2}{8R^2} + \varepsilon^2 \right) \frac{\pi E^* a_{\text{eq}}^2}{8}. \]  
This result shows explicitly how a mismatch strain decreases that adhesion energy between two adhering bodies. When the adhesion energy is reduced to the order of \( k_B T \), adhesion should become unstable against thermal fluctuations.
